

# Bluetooth — A Barn Door?

Thierry Zoller — Security Engineer

## Goal of this Presentation

- > Brief introduction to Bluetooth
  - > History and origin
  - > Function / Services
  - > Difference vs. WiFi (802.11x)
- > Risk potential for enterprises?
  - > How to protect yourself
  - > What needs to be considered
- > What works, what doesn't — Reality Check
  - > Risk transparency
- > Live demos / BTCrack / Mac

## Who are we?

### Kevin Finistere

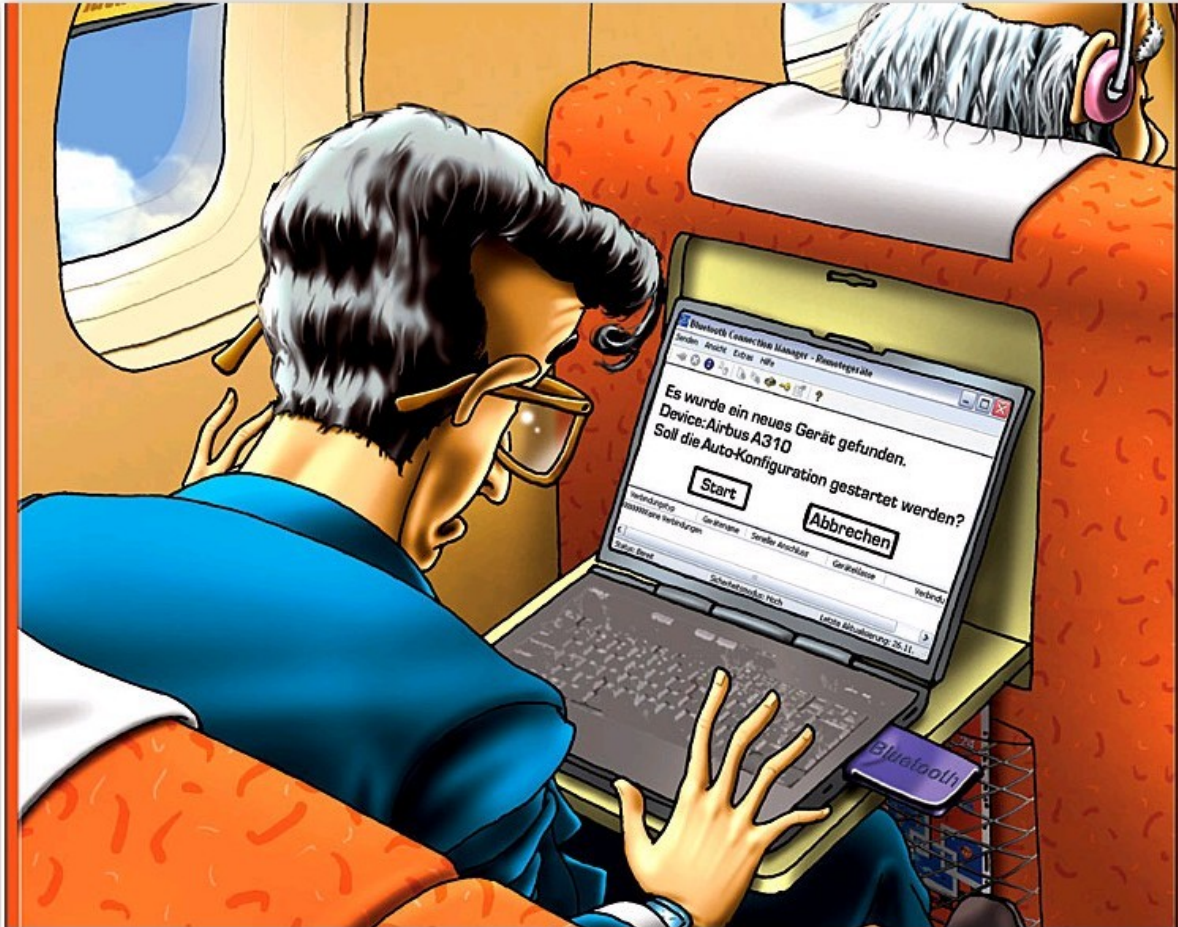

- > Former Head of Research at SNOsoft
- > Vulnerabilities discovered in: Apple, IBM, SAP, Oracle, Symantec
- > Contributed substantially to this talk

### Thierry Zoller

- > Security Consultant @ n.runs AG
- > Vulnerabilities discovered in: Checkpoint, Symantec, Citrix VPN Appliance, MySQL, F-Secure, McAfee, NOD32, and 12 other AV vendors
- > Don't enjoy talking about myself — Google it

# Introduction to Bluetooth

## What is Bluetooth (802.15)?

- > Named after Harald Bluetooth
- > Unregulated ISM band 2.4 GHz (2.400–2.4835 GHz)
- > 79 channels (except France and Spain)
- > Invented by Ericsson (1995) — SIG founded 1998 (Special Interest Group)
- > Over one billion Bluetooth chipsets sold to date (as of 2006)
- > **Goal: low-cost cable replacement, low power — PAN**

## Difference vs. WiFi (802.11x)

- > WiFi 11 channels | Bluetooth 79 channels
- > WiFi SSID broadcast | Bluetooth passive
- > Bluetooth "framework" (installed on every client)
- > Frequency hopping
- > Every Bluetooth participant is both AP and client
- > Range

## Bluetooth has 3 Security Modes

- > Mode 1: device never enters security mode (no security)
- > Mode 2: no encryption, security delegated to the application
- > Mode 3: link is encrypted before any data is exchanged
- > Security Manager

Müssen Sie einen Hauptschlüssel für das Bluetooth-Gerät hinzufügen?

Informationen zur Beantwortung dieser Frage finden Sie im Abschnitt "Bluetooth" der Gerätedokumentation. Wenn die Dokumentation einen Hauptschlüssel enthält, dann verwenden Sie diesen.

Hauptschlüssel automatisch auswählen

Hauptschlüssel aus der Dokumentation verwenden:

Eigenen Hauptschlüssel auswählen:

Keinen Hauptschlüssel verwenden

 Sie sollten immer einen [Hauptschlüssel](#) verwenden, es sei denn, das Gerät unterstützt keinen. Es wird empfohlen, dass der Hauptschlüssel zwischen 8 und 16 Ziffern lang ist. Je länger der Hauptschlüssel, desto sicherer ist die Übertragung.

< Zurück Weiter > Abbrechen

## What is Pairing?

- > Two devices "pair" by authenticating to each other via PIN
- > Keys (E21, E22) are exchanged, generated from device + user input
- > Keys are stored, enabling later connections without re-entering the PIN
- > After pairing, the device no longer needs to be "discoverable"

## 2 Pairing Modes

### > Non-Pairable Mode:

- > Device rejects authentication handshakes (i.e. secured services are inaccessible)

### > Pairable Mode:

- > Device responds with LMP\_accepted and prompts for PIN entry

## 3 Discoverable Modes

### > Discoverable Mode:

- > Device can be found via an inquiry scan

### > Limited Discoverable Mode:

- > Implementation-dependent: often time-based

- > Discoverable to devices on the Trusted list

- > Discoverable to devices on the Paired list

- > Phones are very often in Limited Discoverable mode just after power-on (airports...) without user confirmation. → BD\_ADDR exposed

### > Non-Discoverable Mode:

- > Does not respond to inquiry scans (in theory)

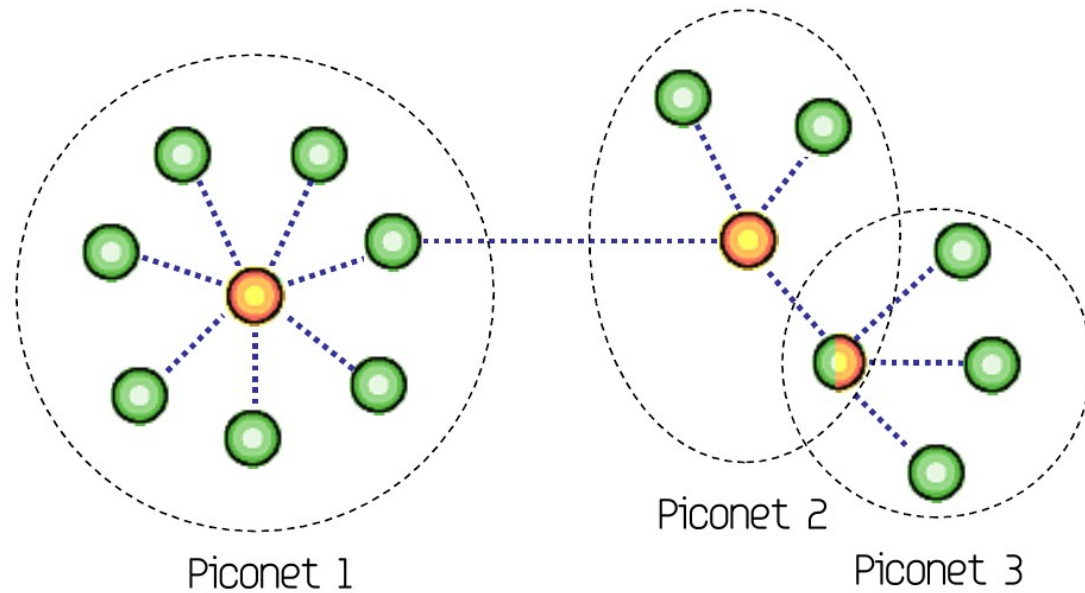

## Bluetooth Addresses

- > Bluetooth address "BD\_ADDR" is a 48-bit MAC address
- > Identifies devices like a MAC address on network gear
- > First line of defence

**00:11:9F:C5:F1:AE**

# PAN — Personal Area Network

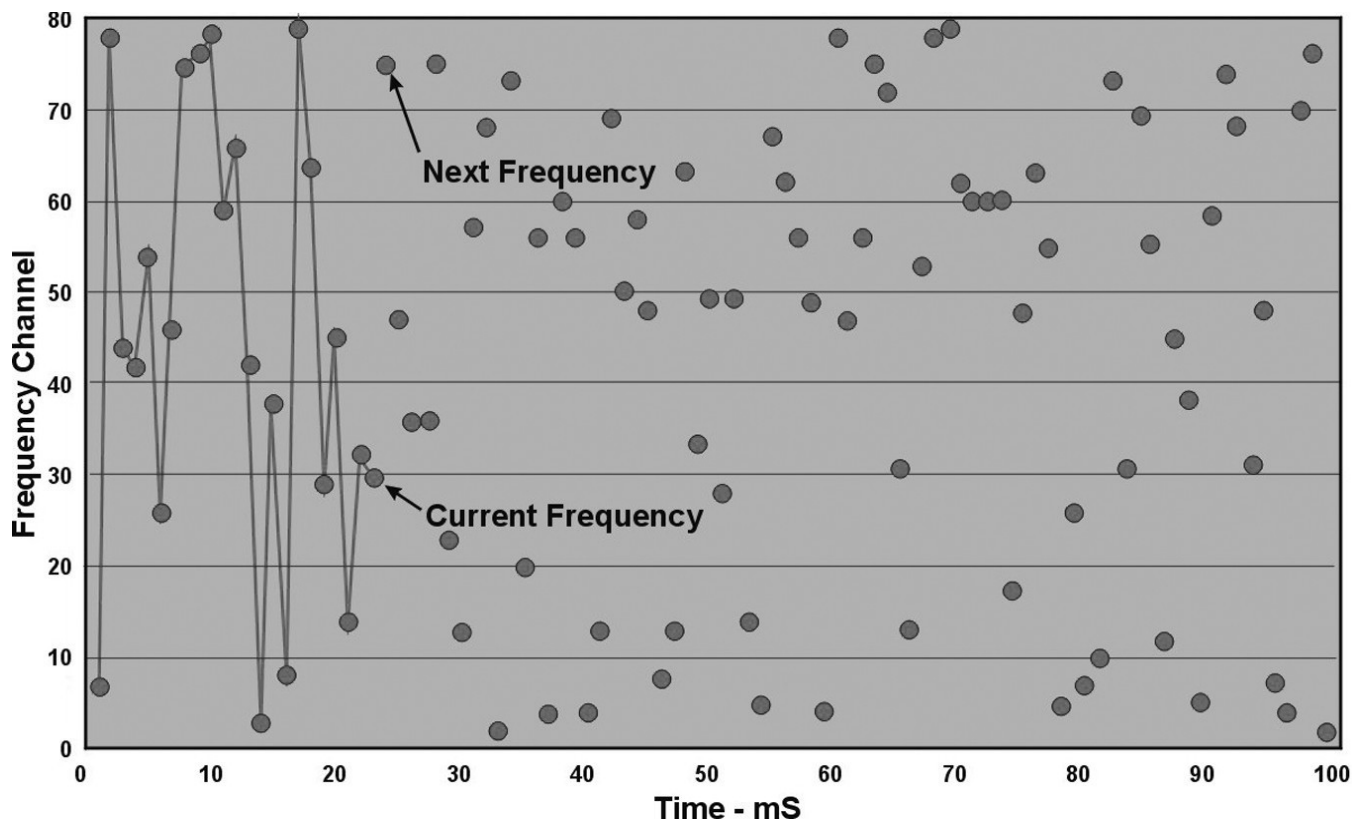

## Bluetooth Frequency Hopping

- > Slaves always synchronise to the master
  - > Per spec, the master is the device that initiates paging
- > Inquiry mode:
  - > Master hops 3200 times/sec
  - > Slave hops passively through preset frequencies
- > Paging / Connected:
  - > Piconet agrees on a hop sequence derived from the BD\_ADDR and the master's clock-offset
  - > Both hop synchronously 1600 times/sec
- > *Passive sniffing is not trivial — frequency changes 1600x/sec. Only someone who knows the hop sequence can sniff or join.*

# Bluetooth Frequency Hopping

## Bluetooth Profiles

- > Define services as a group of options and protocols offered
- > Every Bluetooth device has them
- > Vertical view of the BT stack (enumerated via SDP)
- > e.g. Headset, Imaging, File Transfer, PIM, etc.

# Long-Range Bluetooth

*Bluuueeeetttoooooooooooooottttthhhh*

## Long-Range Bluetooth

- > Modify a commodity BT dongle so an external antenna can be attached. Instructions freely available online.
- > Linksys is ideal

**Class 3**

10 m →

**Class 2**

25 m →

**Class 1**

100 m →

## Long-Range Bluetooth

- > Antrum Lake (USA)
- > 788 metres
- > An old man "stole" the phone; Kevin tracked him with the Yagi.

## Optimised Long-Range Bluetooth

- > Integrated Linksys dongle
- > Integrated USB cable
- > Metallised directional antenna
- > 10x optics
- > Laser (coming soon)
- > Higher penetration through walls

**Bluetooth Signal Wavelength 12,5 cm**

*Experiment: found devices in the building behind the actual target building.*

## Automation

- > Bundled
- > Embedded Linux device (NSLU2)
- > Autonomous scan & attack rig
  - > Searches and archives results
  - > Can attack devices automatically
  - > Stores files and scans on SD card

## Automation

## It's Not Just Toys Using Bluetooth...

- > Industry is jumping on:
  - > Various pumps
  - > Power utilities (UK) →
- > *"The Bluetooth modems have been configured as non-discoverable [...] the RL27 switches are protected from wireless hacking through a 48-bit software encryption key"*
- > *"The operator can make software upgrades, reconfigure the RTUs, [...] from a distance up to 100 metres."*

## Bypassing Bluetooth Security

## BlueBug Attack — Trifinite Group

- > The service that should never have existed
  - > Allegedly an IRDA leftover not intercepted by the Security Manager

## BlueSnarf Attack — Trifinite Group

- > "Get" request implementation over OBEX Push
- > OBEX Push normally Security Mode 1

← OK

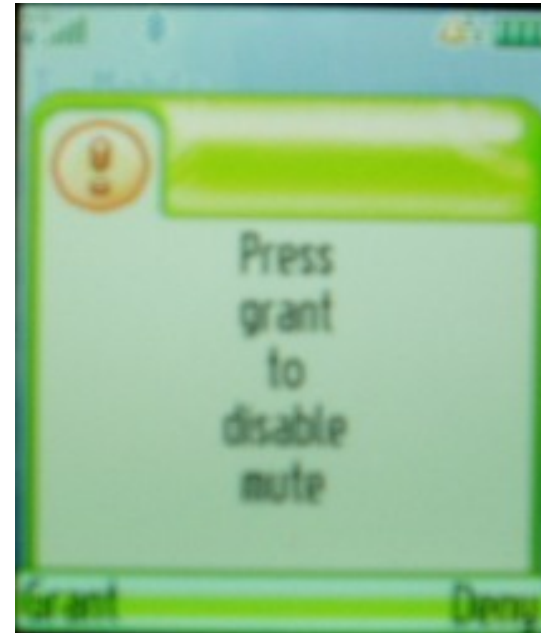

- > Vulnerable devices:

- > Nokia 6310, 6310i, 8910, 8910i; Sony Ericsson T68, T68i, T610, R520m, Z1010, Z600; Motorola V80, V5xx, V6xx, E398; and others...

## The "Please Press Yes" Attack

- > Social engineering
- > Motorola
- > PEBL, V600, Razr, xxx?

### Proof of Concept:

```
hciconfig hci0 name `perl -e  
'print "Press\x0dgrant\x0dto\x0ddisable\x0dmute\x0d\x0d"'`
```

## The PIN Isn't Really a PIN

- > Did you know? Per the spec, the "PIN" is called a Passkey and may contain letters and even diacritics — not just digits.
- > **BUT (almost) NO ONE HAS IMPLEMENTED IT THAT WAY**
- > Imagine if Microsoft had invented NTLM (after LM only allowed [a-z, A-Z, 0-9]) and then forgotten to let users type Umlauts.
- > So brute-forcing a pairing exchange with BTCrack ALWAYS succeeds. Thanks. F-, see me after class.

| Input  | Bluetooth Internal                 |
|--------|------------------------------------|
| 0123   | 0x30 0x31 0x32 0x33                |
| Ärlich | 0xC3 0x84 0x72 0x6c 0x69 0x63 0x68 |

## "Eavesdropping"

- > Root cause:
  - > Discoverable mode
  - > Pairing mode
  - > Hard-coded PIN
- > Laptops / PDA / Widcomm
- > Real-time patch for CarWhisperer
- > Windows native tooling

```
SWITCH: for ($bdaddr) {
  /00:02:EE/    && do { $pin="5475"; last;}; # Nokia
  /00:0E:9F/    && do { $pin="1234"; last;}; # Audi UHV
  /00:80:37/    && do { $pin="8761"; last;}; # O'Neill
  /00:0A:94/    && do { $pin="1234"; last;}; # Cellink
  /00:0C:84/    && do { $pin="1234"; last;}; # Eazix
  $pin="0000"; # 0000 is the default passkey in many cases
}
```

## What the #!@#!! Is My Mouse Doing?

- > HID = Human Interface Device
- > Bluetooth service profile
  - > HID server (PC)
  - > HID client (keyboard & mouse)
  
- > PSM channel 3 (PSM\_Scan — Connect Success)
- > Inject keystrokes (as if someone were sitting at the PC)
- > Root cause:
  - > Non-secure mode
  - > Discoverable mode
- > PoC: Collin Mulliner — HidAttack

## What the #!@#!! Is My Mouse Doing?

- > Encryption rarely used
- > Sometimes no authentication (no Security Mode 3)
- > Sniffing keystrokes
- > Root cause:
  - > Discoverable
  - > Without authentication (or hardcoded PIN???)

| All Protocols | Baseband | LMP   | L2CAP | SDP      | BT-HID                 | Data               | HID        |  |
|---------------|----------|-------|-------|----------|------------------------|--------------------|------------|--|
| B...          | Frame#   | Role  | Addr. | ReportId | Report                 | HID Data           | Frame Size |  |
| ●             | 327      | Slave | 1     | Keyboard | Keyboard h             | 0x 01 00 00 0b ... | 22         |  |

| Report ID: Keyboard |                                     |
| HID Report:         |                                     |
| : Keyboard t        |                                     |

## Exploring Internal Networks (1)

- > Or: "How does typing ../ even work here?"
- > File systems freely accessible (!)
- > Sometimes ROOT access (and onto the internal network, if the PC is wired)
- > All known Windows drivers are or were affected
- > Updates often impossible (Broadcom < Widcomm)
- > Affected/still affecting: Windows, Mac, PocketPC, Linux, Unix

### Example against a Pocket PC:

```
# ./ussp-push 00:11:B1:07:BE:A7@4
trojan.exe
..\..\..\..\..\windows\startup\trojan.exe
connected to server
Sending file: ..\..\..\..\..\windows\startup\trojan.exe,
path: trojan.exe, size: 18009
Command (01) has now finished
```

## Exploring Internal Networks (2)

- > Mac OS X 10.3 & 10.4 Vanilla
- > Patch issued a year ago
- > OSX.Inqtana
- > Remote root over Bluetooth

- > Worked not only on Apple machines but also on Windows PCs for a long time
- > Root cause:
  - > ObexFTP → no authentication
  - > Discoverable mode
  - > Directory traversal (!)

## Demo

*If it actually works...*

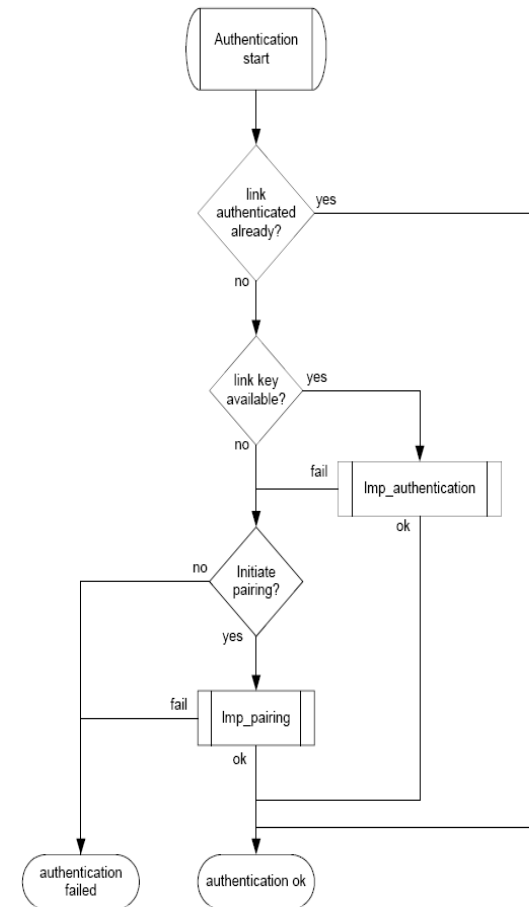

*Thanks to the burglar #!?*

They're only  
implementation  
bugs.

## We Don't Care About the PIN

- > The link key is more important from the attacker's perspective
- > Why?
  - > The link key alone is enough to authenticate
  - > Only required when in pairing mode or discoverable mode
  - > Encryption key (E0) is derived from the link key
  - > One LK grants access to both devices
- > Protocol 1.2 – 2.0 Authentication:

## Finding Devices in Non-Discoverable Mode?

- > Device must be actively communicating with another device
- > PM\_ADDR, AM\_ADDR
- > Target: BD\_ADDR — 48-bit

**00:11:9F:C5:F1:AE**

- > Set sniffer to a fixed frequency, sniff the preamble, extract the channel access code
- > Read the error-correction field (baseband header — 10-bit CRC)
- > First 8 bits assumed 00 (after OUI)
- > Brute-force the remaining 8 bits (should be fast and reliable)

## E0 Encryption

- > "E0 is designed as a new cipher suite for Bluetooth"
  - > "New cipher suite" = uh-oh
- > **E0 should have a strength of  $2^{128}$**
- > **E0 was reduced to  $2^{38}$  strength! (collisions)**
- > E0 ↔ WEP: guarantees privacy but not security
- > Checking whether E0 is in use? (see frequency hopping)
  - > Often not the case at all
  - > "Hardware" sniffers (FTS, BPA100, BPA105, Merlin)
- > What strength? Spec mandates country-specific strengths.

## BTCrack — heisec Release

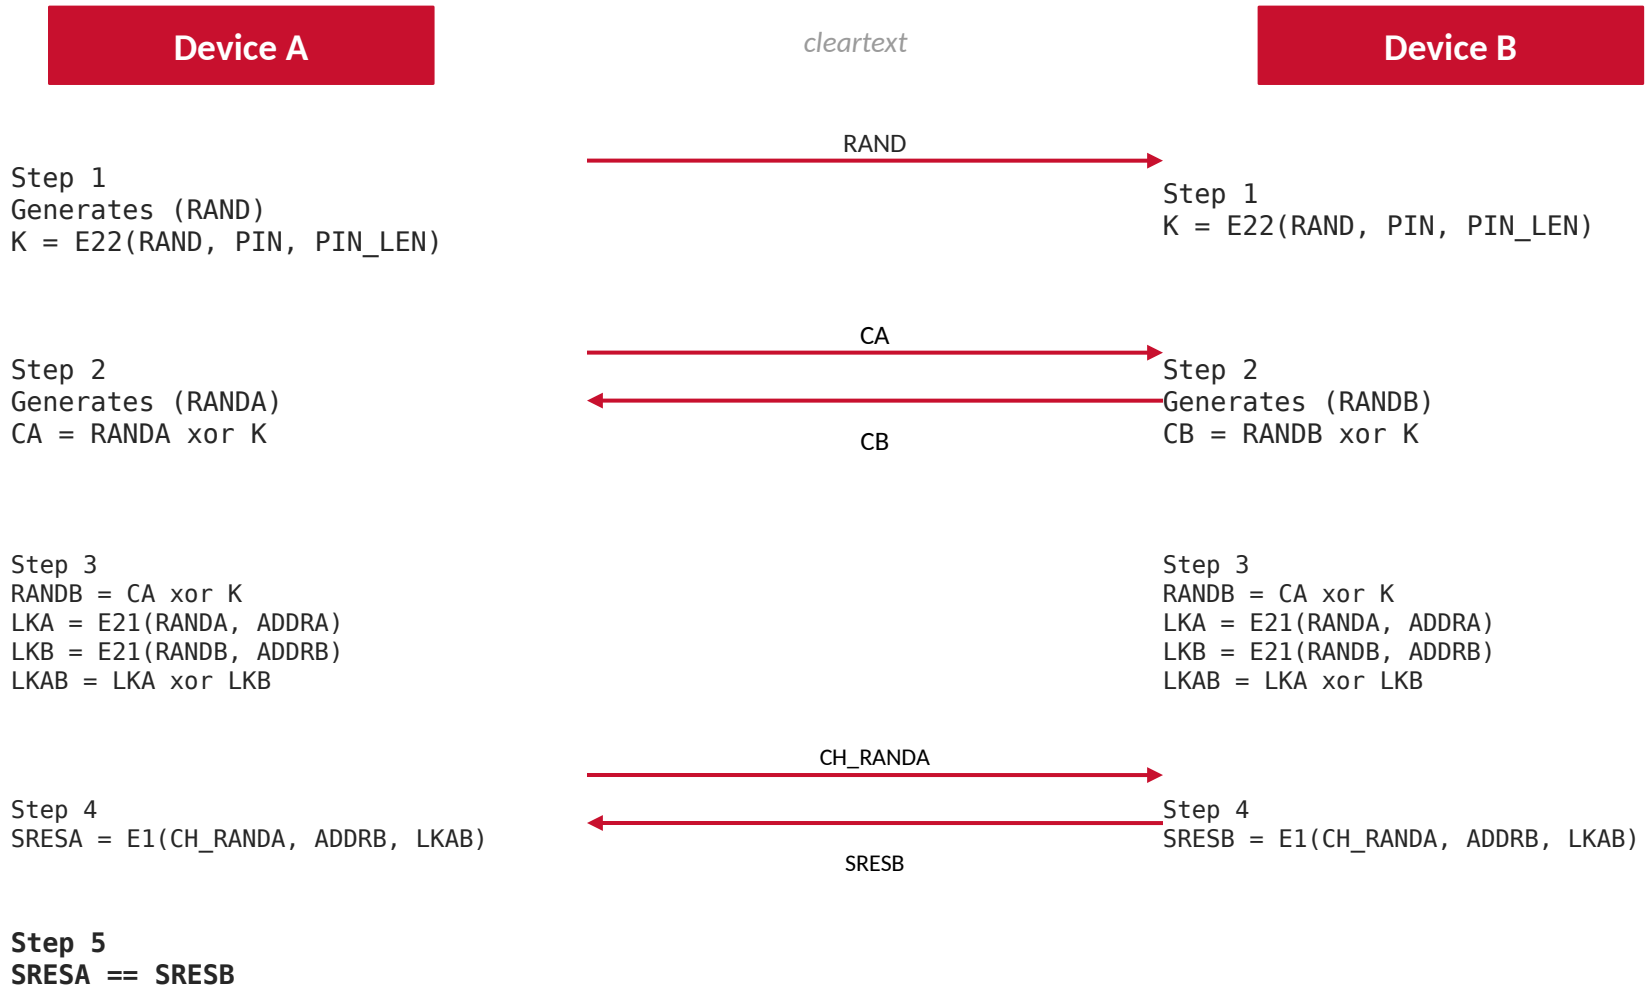

- > What is BTCrack?
- > What's new?
  - > Minor bug fixes
  - > Software speed: 185,000 → 200,000 keys/sec
- > Collaboration with PICOComputing (David Hulton)
- > FPGA support:
  - > E12 @ 75 MHz = 10,000,000 keys/sec
  - > E12 @ 50 MHz = 7,610,000 keys/sec
- > SuperCluster = 15 FPGA boards
  - > <http://www.picocomputing.com>

### Results:

- 4-digit PIN: 0.035 s
- 5-digit PIN: 0.108 s
- 6-digit PIN: 4.312 s
- 8-digit PIN: 117 s (FPGA: 5.6 s)
- 9-digit PIN: 1318 s (FPGA: 101 s)

## Pairing Handshake

## BTCrack — heisec Release

```

Pin = -1;
Do
{
    PIN++;
    CR_K = E22(RAND, PIN, length(PIN));

    CR_RANDA = CA xor CR_K;
    CR_RANDB = CB xor CR_K;

    CR_LKA = E21(CR_RANDA, ADDRA);
    CR_LKB = E21(CR_RANDB, ADDRB);

    CR_LKAB = CR_LKA xor CR_LKB;

    CR_SRES = (CH_RAND, ADDRB, CR_LKAB);
}
while (CR_SRES == SRES)
    
```

Shaked & Wool logic:

## Demo

## But Don't I Need Expensive Hardware?

- > Hardware sniffing was a myth — in reality almost everything runs on the software side
- > What you need:
  - > Dongle with CSR chipset and flash
  - > e.g. CSR BC4 chipset
  - > Firmware from a "three-letter" vendor
  - > Linux tools: dfutool and bccmd
  - > Google: "Busting the Bluetooth Myth"
  - > Google: "Bluetooth Security seems to be very good compared"
- > Since this method was disclosed by Max Moser, expect some novelties soon:
  - > Layer 1-7 fuzzer
  - > Open-source sniffer GUI
  - > Improved hop-sync

**BUSTED**

## Reality Check

- > First-hand experience:
  - > Implementation flaws are always and easily exploitable (hardcoded PINs, BlueSnarf, etc.)
  - > Right now the pairing attack works reliably only under lab conditions. Reason: the commercial solution is poor and the range is short. With unlimited attempts it works in reality too. (We're working on it.)
  - > Devices in non-discoverable mode can be found (Redfang etc.) but it takes a lot of time and patience. Mobile target: barely feasible; stationary: feasible.
  - > Reconstructing the BD\_ADDR with passive methods is feasible, but again limited by the meagre commercial gear. Yagi + flashed dongle + software works better.
  - > Simply "recording" conversations via headset is not as easy as claimed — unless you have the link key, and then you're back to the commercial-gear problem.

## How Do We Protect Ourselves?

- > Company policy → ban Bluetooth
- > Vista Device GPO → Bluetooth USB dongles
- > XP & XP SP2 → third-party software
  - > Built-in chipsets
- > If Bluetooth really must be present:
  - > Update drivers — they are NOT updated through WSUS (unless using the Microsoft BT stack, since SP2). Push them.
  - > Non-discoverable mode (and disable automatic scanning)
  - > Harden BT services — set ALL to "Secure", disable unnecessary ones (Headset, Imaging, ...)
  - > Even with services disabled, the client can still call them outbound (so information leakage cannot be eliminated this way)
- > Bluetooth 2.1

## Summary

- > Every Bluetooth-equipped device (PC, laptop) could inadvertently provide access into the internal LAN — and do so with native tooling (WiFi would require custom code, RCE aside)
- > Bluetooth should be treated as a server protocol, not a client protocol — services are offered to the outside world and every one has potential weaknesses.
- > Bluetooth bypasses your firewall, IDS, and other security infrastructure. Local firewalls don't protect the stack — I'm aware of no TDI drivers for Bluetooth that would.
- > Bluetooth 2.1 shakes things up considerably on the security front:
  - > Elliptic-curve cryptography
  - > Near-Field Communication
  - > Implementation flaws? (TO-DO)
  - > Will it be any good?

# Bluetooth — A Barn Door? > Kick out
